
Part 01

1. Design and implement a Class for the employees in a company:

Notes:

- Employee is identified by an ID, Name, security level, salary, hire date and Gender.
- We need to restrict the Gender field to be only M or F [Male or Female]
- Assign the following security privileges to the employee (guest, Developer, secretary and DBA) in a form of Enum.
- We want to provide the Employee Class to represent Employee data in a string Form (override ToString ()), display employee salary in a currency format. [Use String.Format() Function].

2. Develop a Class to represent the Hiring Date Data:

- Consisting of fields to hold the day, month and Years.

3. Create an array of Employees with size three a **DBA**, **Guest** and the third one is **security officer** who have full permissions. (Employee [] EmpArr;)

Notes:

- Implement All the Necessary Member Functions on the Class (Getters, Setters)
- Define all the Necessary Constructors for the Class
- Allow NO RUNTIME errors if the user inputs any data
- Write down all the necessary Properties (Instead of setters and getters)

4. Sort the employees based on their hire date then Print the sorted array.

- While sorting (how many times Boxing and Unboxing process has occurred)
